Enchondromas, which are benign cartilage tumors, tend to settle in the small bones of the hands and feet. Enchondromas usually occur solitarily and are non-cancerous lesions. Involvement of the thoracic wall is rare and usually occurs on the costal surfaces. Enchondromas rarely develop into chondrosarcomas. Complete surgical excision is the treatment of choice for these tumors because of malignant degeneration. 1, 2 It should be kept in mind that enchondroma may rarely mimic neurogenic tumors by localizing in the posterior mediastinal area.
